

Δ wealth per capita, predicted (\$k, 2023)

Actual vs. predicted tract wealth change, test cities (36 CBSAs, 3,700 tracts). Each tract pairs its latest year t_1 with the earlier year closest to $t_1 - 10$ (gaps: 2y: 6; 3y: 4; 4y: 1; 5y: 580; 6y: 2,454; 7y: 655). In every city-year, predicted and ACS label ranks are mapped to dollars through a GB2 fitted to that city's ACS W2 tract wealth that year (2023 dollars,

CPI-U), so $R^2_{00s} = 1 - \text{SSE}/\text{SST}$ needs no refit. (A) Dollar change; (B) log change. Within-city: both sides demeaned by CBSA. Rank-frozen: the tract's t_0 predicted rank carried to t_1 's GB2 — no t_1 imagery, so its R^2 comes from the GB2 maps alone. Brackets: 95% city-cluster bootstrap CIs.

Benchmark — Khachiyan et al. (2022), Table 2, income, no initial conditions, R^2 of Δ log total personal income: 2000–2010 (in-sample): 0.43; 2007–2017 (out-of-sample): -0.10; 2000–2017 (out-of-sample): 0.37. Unlike theirs, the GB2 map at t_1 uses that year's ACS city distribution. Axes show the central 99.5% of each marginal; 77 points fall outside and are not shown.
